

Approach and Plan

Approach and Plan

Strategy Overview

My goal is to address every issue from the codebase review quickly without sacrificing quality. I will use a deliberate “nuke → scalpel” flow: let AI handle bulk implementation, then refine the changes with targeted manual edits, add a final-touches plan, and validate everything with hands-on testing and a clean-room rerun.

Execution Strategy

Step 1: Feedback Documentation

Estimated Time: 30-45 minutes

Action: Personally and deliberately write all feedback in a clear, structured format

Rationale: Well-documented feedback ensures: - No issues are missed or misunderstood
- AI tools have clear context for each fix - Future reference is possible if questions arise - Consistency in addressing similar issues

Step 2: Nuke Pass with Claude Code

Estimated Time: ~1.5-2 hours

Action: Feed Claude Code the full, explicit checklist from `Feedback.md` and implement fixes in bulk

Rationale: Quickly moves the app from broken → functional and surfaces integration issues early.

Step 3: Scalpel Pass with Cursor

Estimated Time: ~1-1.5 hours

Action: Make micro-level edits—tighten UX, fix edge cases, and align behavior with the intent of each feedback item

Rationale: Adds precision where bulk AI changes need human judgment.

Step 4: Thinking-Model Report for Final Touches

Estimated Time: ~30-45 minutes

Action: Generate and refine a short plan for final touches, including: - **Data encryption:** Will be added because of my question about the client's desire for privacy and data safety during our interview. The plan calls for AES-256-GCM encryption of sensitive health fields (sleep scores, durations, caffeine amounts) at rest, with backend-managed decryption for authenticated sessions. - **Oura Ring integration:** Will be added at the interview assignment's request. The plan specifies OAuth2 flow, encrypted token storage, and automatic data syncing (with device access required for validation). - **Demo mode:** Will be activated as a fallback for failed or unavailable Oura Ring integration. The plan includes realistic data generation and a toggle between demo and live data to showcase core functionality without hardware.

Rationale: Ensures the enhancement work is scoped, feasible, and aligned with interview requirements and product risk.

Step 5: Second AI + Micro-Edit Cycle

Estimated Time: ~45-60 minutes

Action: Use Claude Code to implement the final-touch solutions, then refine them in Cursor: - **Data encryption:** Implement AES-256-GCM encryption for sensitive health data fields so data is encrypted at rest and transparently decrypted for authenticated sessions. - **Oura Ring integration:** Implement OAuth2 flow, encrypted token storage, and automatic data syncing; note that full validation requires device access. - **Demo mode:** Build a demo system with realistic sample data and a toggle to switch between demo and live data, acting as a fallback when Oura is unavailable.

Rationale: Keeps implementation fast while preserving codebase conventions and quality.

Step 6: Manual QA Pass

Estimated Time: ~20-30 minutes

Action: Test the app end-to-end to catch regressions and UX issues

Rationale: Verifies real behavior beyond AI-implemented changes.

Step 7: Final Safety Net

Estimated Time: ~20-30 minutes

Action: Reclone the repo and have Claude Code complete the assignment from scratch, then merge any gaps

Rationale: Clean-room verification to reduce missed issues and confirm completeness.
